

Performance and safety evaluation of a human sized FFL imager concept

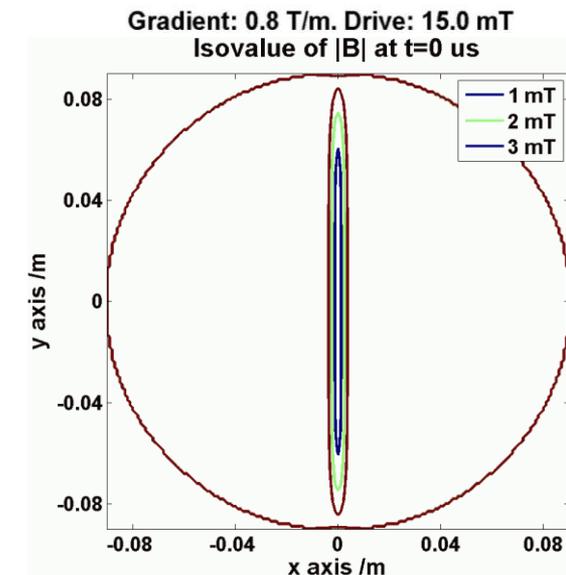

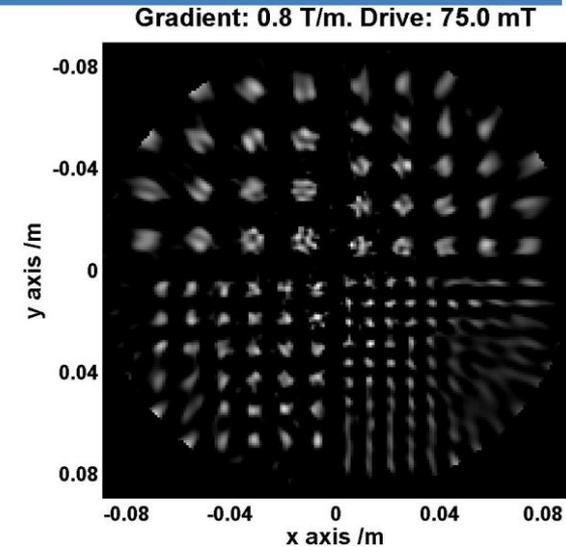

Gael Bringout, Ksenija Gräfe, Thorsten M. Buzug

Institute of Medical Engineering
Universität zu Lübeck
Director: Prof. Dr. T. M. Buzug

Motivation - I

Two effects limit the Field Of View (FOV) for a Human sized FFL imager:

- the drive field amplitudes are limited to a few mT due to Peripheral Nerve Stimulation (PNS),
- the low field volume looks like a banana when moving the line near the border of the coils.

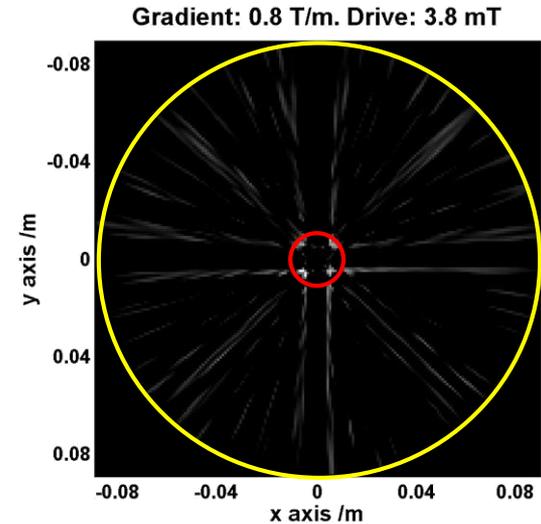

Motivation - II

How could we increase the FOV?

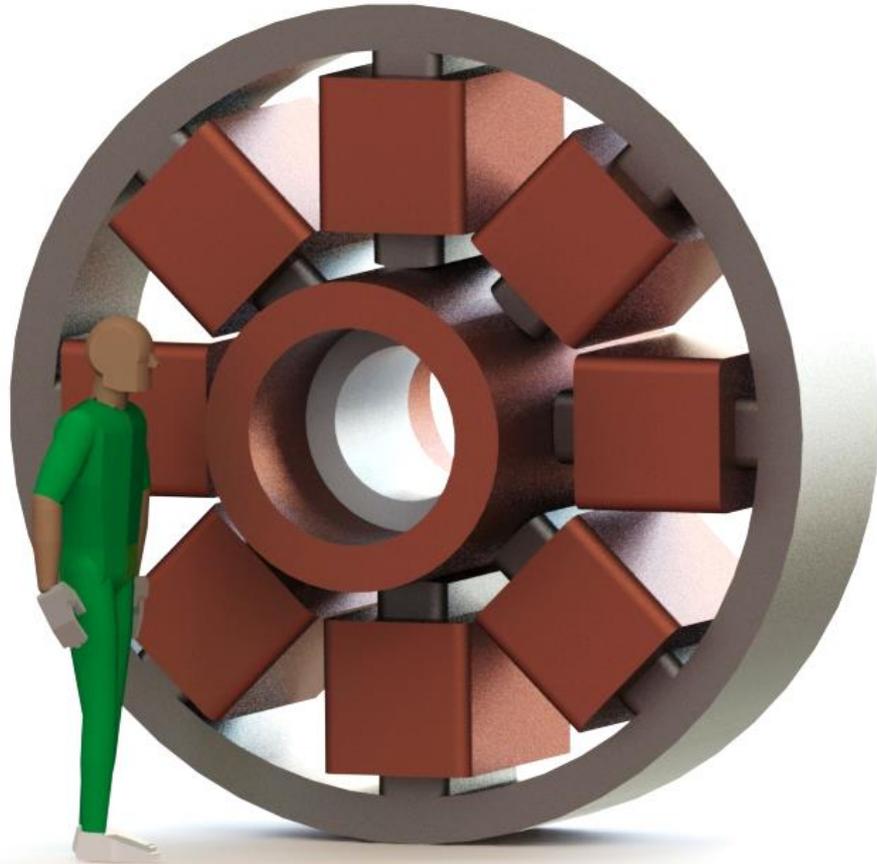

With which sequence?

Does the banana effect play a significant role?

Are PNS likely to happen?

Which imager? Higor

Scanner with a 1 T/m gradient on the line:
Quadrupoles:

- Inner diameter: 1 m
- Magnetomotive force: 81 kAT
- Current density: 3 A/mm²

Solenoid:

- Inner diameter: 0.7 m
- Length: 1.5 m
- Dissipated power: 2 * 65 kW

Drive:

- 2D
- Inner diameter: ~0.50 m

Focus:

- Using the pole of the quadrupole
- Current density: unknown

An FFL sequence using focus fields

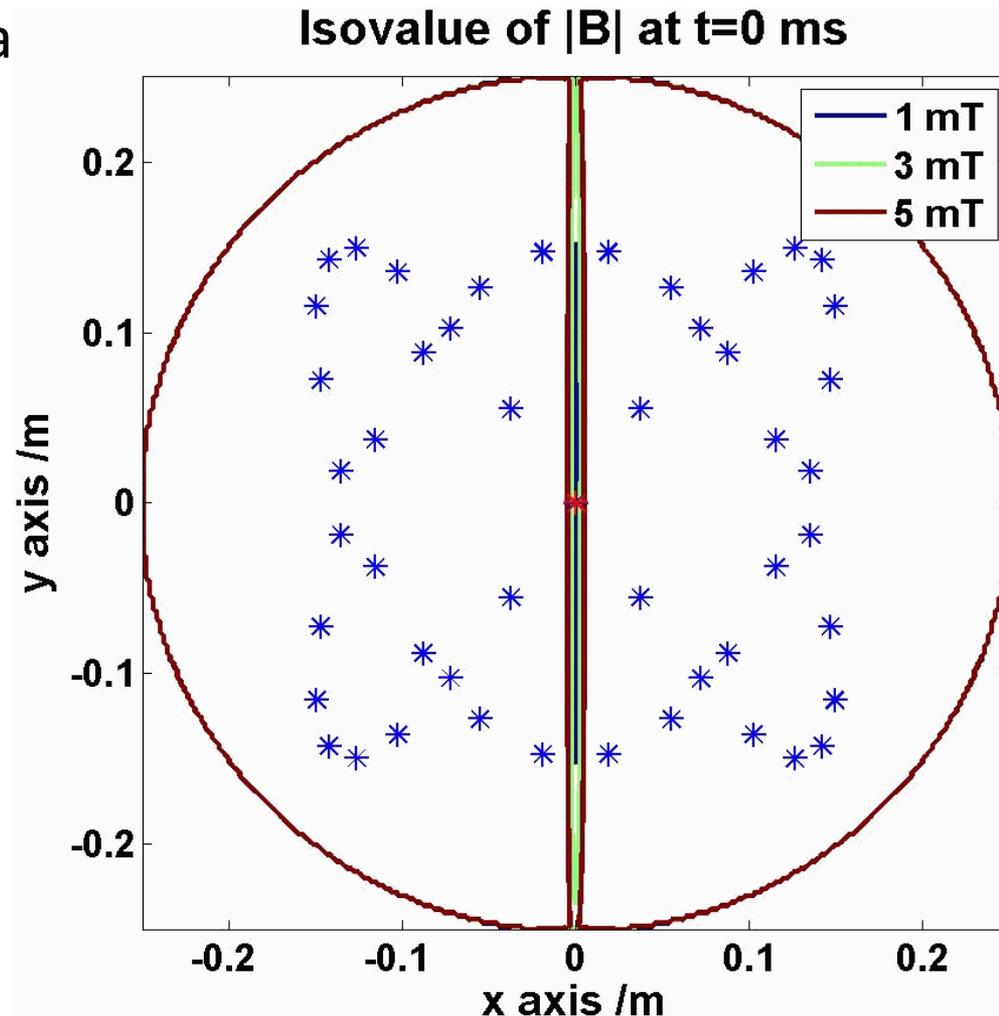

In order to acquire one image with a fully resolved spectrum we:

- move the rotation centre 3 times around the Lissajous curves,
- rotate the line 2 times using a 2π rotation.

The Lissajous curve is made with frequencies of 90 and 60 Hz.

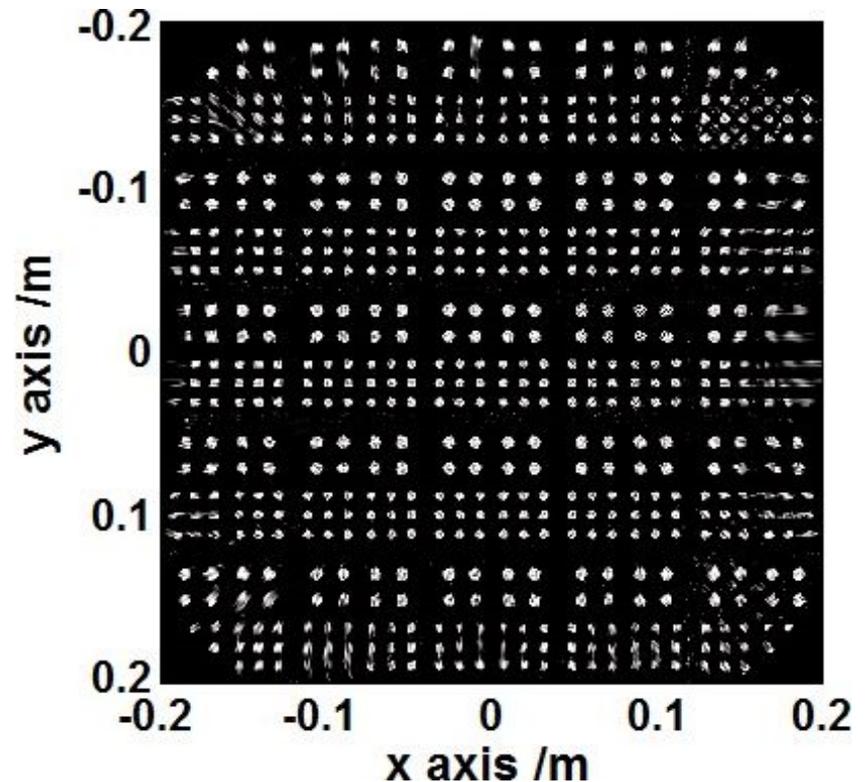

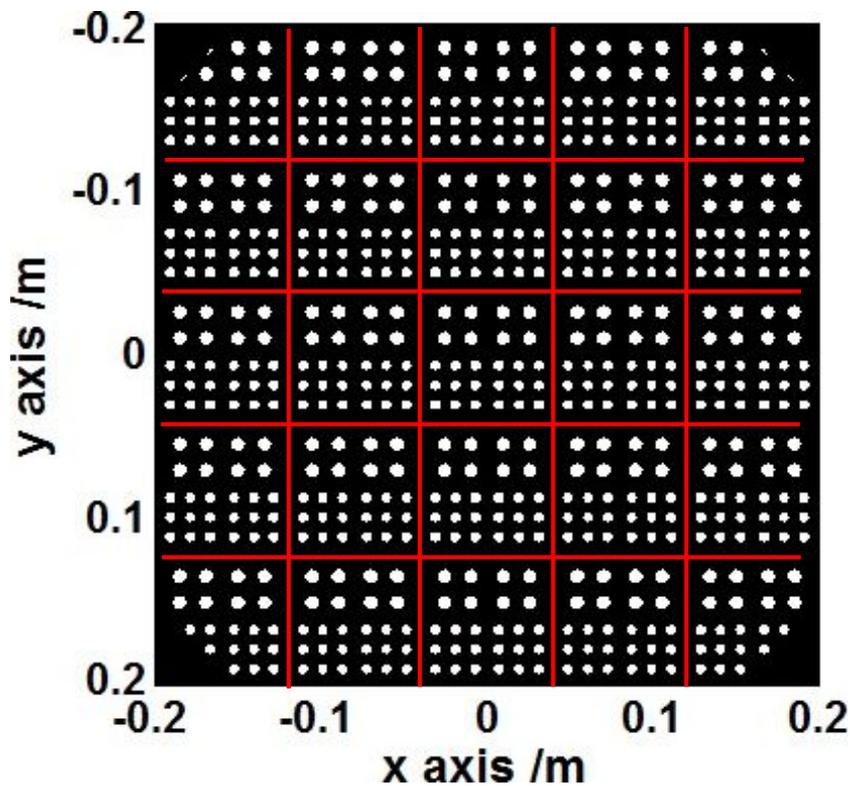

Quadrupoles are used with a frequency of 40 Hz.

10 acquisitions per second.

Reconstruction

- Area divided in 25 sections (limited by the available RAM – 1 TB)
- Reconstructed with a modified ART (filter imaginary & negative solutions)
- No regularization

Signal structure

With a drive frequency of 150 kHz, the system matrix looks like:

300 010 Hz

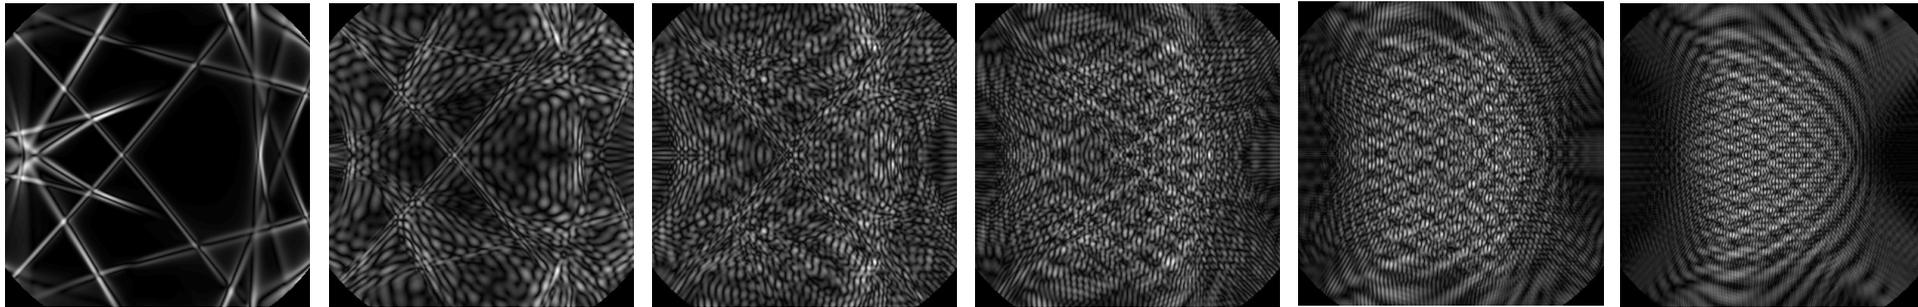

302 040 Hz

304 100 Hz

306 100 Hz

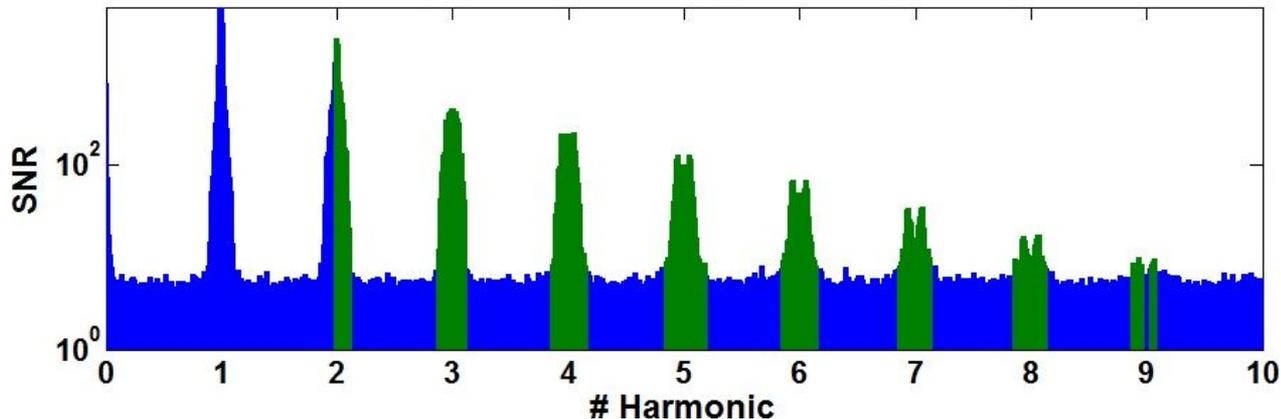

308 620 Hz

312 890 Hz

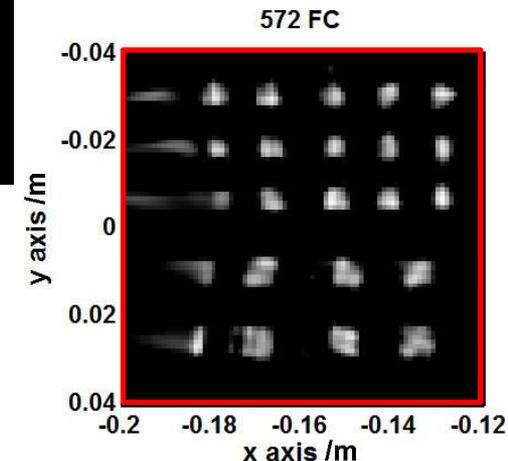

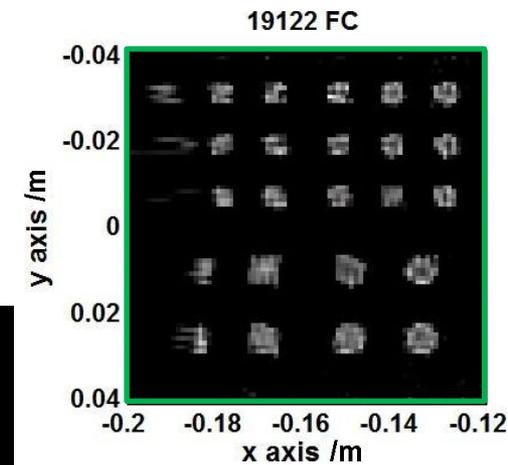

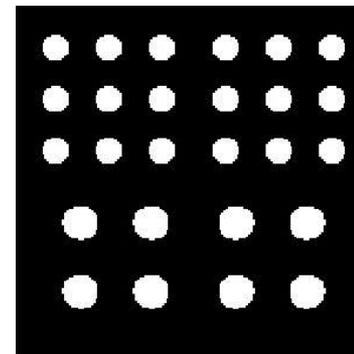

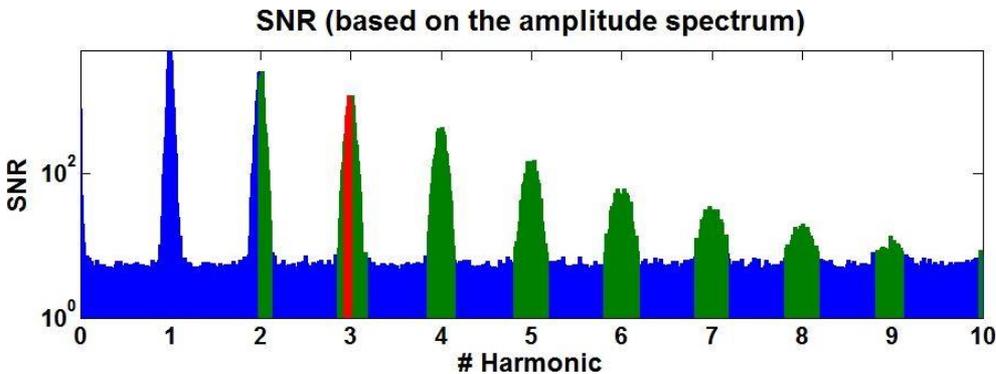

The simulated signal for a section looks like:

SNR (based on the amplitude spectrum)

Signal amplitude

Using the FC with an SNR above 1/10 of the maximal SNR around the 3rd harmonic (the red one), 572 FCs are selected.

Safety: Can we put a patient inside Higor?

Drive coils

- 3.7 & 4.8 mT Amplitude peak
- 150 kHz
- Ok

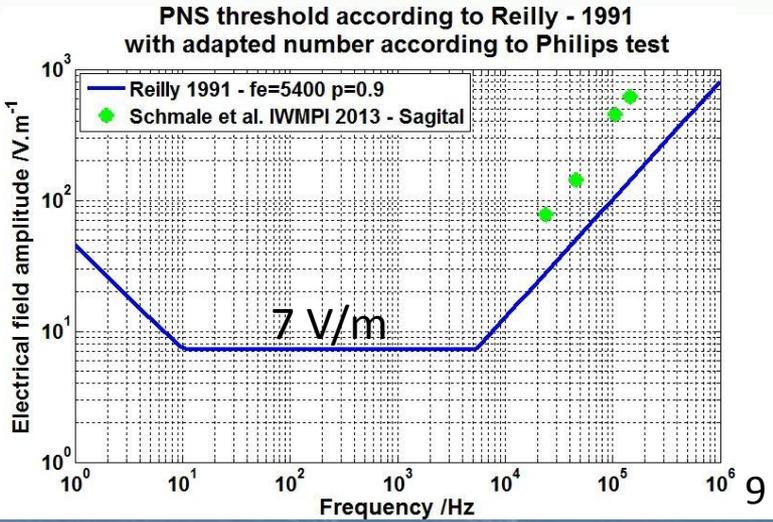

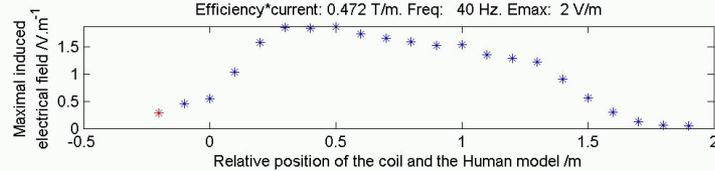

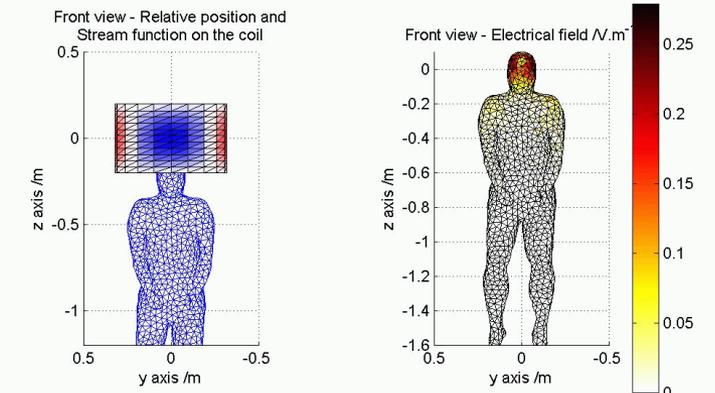

Quadrupole

- 0.5 T/m
- 40 Hz
- ~3 V/m: Reilly 1991 – could be ok

Focus

- 320 mT peak
- ~90 Hz
- ~32 V/m: Reilly 1991 – not ok

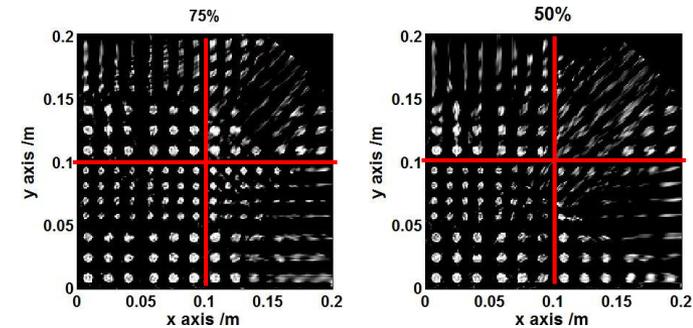

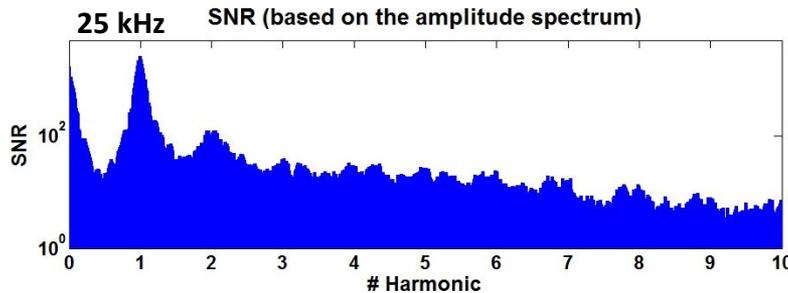

And together?

Future work

Explore other possibilities:

- reduce the focus fields amplitudes,
- reduce the drive frequency.

Improve the concept by:

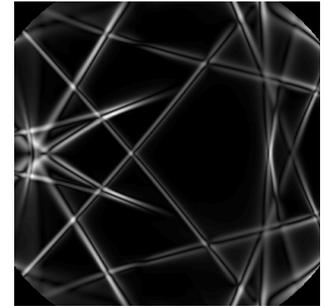

- generating enough magnetic fields for the focus fields. Saturation of the core is a limiting factor,
- experimentally defining the PNS thresholds for low frequencies,
- experimentally defining the PNS thresholds for a sum of fields & frequencies.

Conclusion

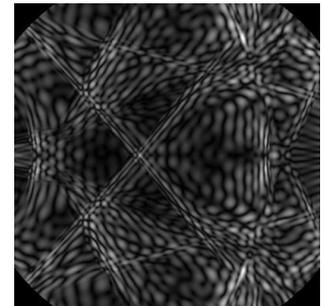

For a human sized FFL imager using focus fields and the presented sequence:

- a large FOV can be covered,
- current functions are continuous,
- 10 images per second could be acquired,
- field quality is not an issue
- more knowledge about the PNS thresholds should be gathered,
- flexibility on the choice of frequencies, huge impact on MPI-signal structure.

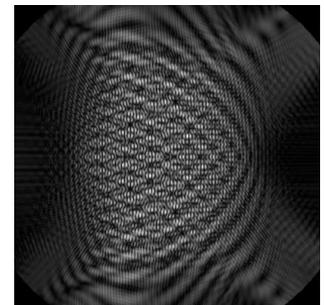

300 010 Hz

302 040 Hz

312 890 Hz

Low and high frequencies mixing

- Does it work as simulated?

Some reco parameters

- Langevin particle – 30 nm – Fe₃O₄
- Concentration phantom: 1.5 mol. m⁻³ (Resovist, 10 times diluted)
- noise's amplitude spectral density: 56 pV/ $\sqrt{\text{Hz}}$
 - 30 times more than the patient noise limits from Weizenecker 2007 – A simulation study [...]
- Resolution:
 - System matrix: 1 mm
 - Phantom: 0.5 mm
